Oops... Shall we try again?
Lab

(level 2)
(level 1)
        protect inputs from user stupidity

**(Level 3)**

Description:
        The function of this program is to create an overloaded function that
allows the user to pass a prompt, an error message, and bounds. The function
will prompt the user until they give a proper value to what the program was
looking for and use the error message passed to prompt the user. This function
is able to be used for doubles, longs, and characters.

Thought Provoking Questions:

Q1.How can you pass a prompt or error message to a function as an argument

A: The messages can be passed simply as strings (either the programmer uses a
   literal string or passes a string variable)

Q2.How do you pass a string to a function? Will the strings need to be changed
  What care do you need to take for these arguments, then?

A: A literal string passed, or a string variable. The function can let the
   user choose how to format the prompt and error so the strings don't need
   to be changed. Since the strings are not changed in the function, they
   should be passed as constant call by reference.

Q3.How do you pass a list of values to a function? Will the elements need to be
   changed here? what care do you need to take for these arguments then?

A: A list of values can either be passed as a vector or an array (I used a vector
   because I am more familiar with vectors). The element won't be changed so it
   can be passed as a constant call by refernce.

Q4.What other arguments does each function take? Are the changed? What special
   care should you take with them?

A: All the arguments can be passed as constants because they're not altered.
   the function will take a prompt, an error message, and some type of limit
   (either lower, upper, both, or a list)

Q5.What value is returned by your functions? What type is it and what does it
   represent?

A: The value returned by the function is the same as the data type of the limits
   passed (double, long, char). The value represents a the input of the user
   that was valid according to the parameters of the validation (and correct
   data type)

Q6.What care does a caller of your function have to take with this return value?
   (Can they immediately assume it is a valid entry?)

A: The caller can immediately assume it's a valid entry because the input
   validation function should have taken care of any invalid values. the caller
   either has to assign it directly to a variable or can print it directly
   (in the case of my driver)

Q7.How does the compiler distinguish which of your functions is being used for
   a particular call? (They ALL have the same name, after all...)

A: The compiler can check the data type of the limits in order to distinguish the
   function. The upper limit and lower limit functions can be distinguished by
   position of the limit in the arguments for simplicity (only adds a little bit
   of complexity when calling the function... oh well) functions with an upper
   and lower limit will have an extra parameter compared to the other 3 functions
   of the same data type

Q8.How do you protect your library from being circularly included?

A: In the header file use ifndef then define to protect from circular inclusion.
   this will stop the "circle" if it sees it is defined already

Q9.What changes are needed in your main application (the test application here) to
   get it to work with the library? What about the compiling process?

A: In order to get the main application to work with the library the header file
   needs to be #included and when compiling the libary file will need to be
   compiled alongside the driver or whatever application being used.

Q10.How many files does your libary consist of? What are the? Which one(s) do you
   #include?

A: The library consists of the interface file (.h) and the implementation file (.cpp)
   only the .h file will be included
